NOTES
[1]Temperature Ranges are J, K, L Versions: –40°C to +85°C

A, B, C Versions: –40°C to +85°C

S, T, U Versions: –55°C to +125°C

[2]Specifications applies to both DACs in AD7528.

[3]Guaranteed by design but not production tested.

[4]Logic inputs are MOS Gates. Typical input current (+25°C) is less than 1 nA.

[5]These characteristics are for design guidance only and are not subject to test.

[6]Feedthrough can be further reduced by connecting the metal lid on the ceramic package (suffix D) to DGND.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS
(T_A = +25°C unless otherwise noted)

V_{DD} to AGND . . . . 0 V, +17 V

V_{DD} to DGND . . . . 0 V, +17 V

AGND to DGND . . . . V_{DD} + 0.3 V

DGND to AGND . . . . V_{DD} + 0.3 V

Digital Input Voltage to DGND . . . . –0.3 V, V_{DD} + 0.3 V

V_{PIN2}, V_{PIN20} to AGND . . . . –0.3 V, V_{DD} + 0.3 V

V_{REF} A, V_{REF} B to AGND . . . . ±25 V

V_{RFB} A, V_{RFB} B to AGND . . . . ±25 V

Power Dissipation (Any Package) to +75°C . . . . 450 mW

Derates above +75°C by . . . . 6 mW/°C

Operating Temperature Range

Commercial (J, K, L) Grades . . . . –40°C to +85°C

Industrial (A, B, C) Grades . . . . –40°C to +85°C

Extended (S, T, U) Grades . . . . –55°C to +125°C

Storage Temperature . . . . –65°C to +150°C

Lead Temperature (Soldering, 10 secs) . . . .+300°C

CAUTION:
1. ESD sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.

2. Do not insert this device into powered sockets. Remove power before insertion or removal.

TERMINOLOGY
Relative Accuracy
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full scale and is normally expressed in LSBs or as a percentage of full scale reading.

Differential Nonlinearity
Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB max over the operating temperature range ensures monotonicity.

Gain Error
Gain error or full-scale error is a measure of the output error between an ideal DAC and the actual device output. For the

AD7528, ideal maximum output is V_{REF} – 1 LSB. Gain error of both DACs is adjustable to zero with external resistance.

Output Capacitance
Capacitance from OUT A or OUT B to AGND.

Digital to Analog Glitch lmpulse
The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with V_{REF} A, V_{REF} B = AGND.

Propagation Delay
This is a measure of the internal delays of the circuit and is defined as the time from a digital input change to the analog output current reaching 90% of its final value.
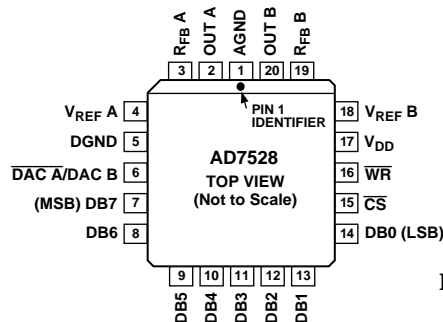

Channel-to-Channel Isolation
The proportion of input signal from one DAC's reference input which appears at the output of the other DAC, expressed as a ratio in dB.
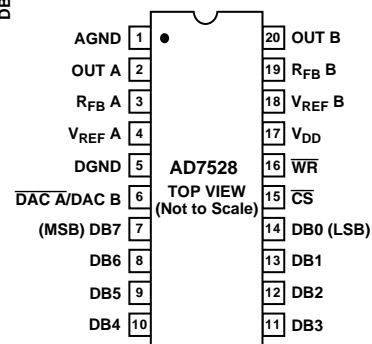

Digital Crosstalk
The glitch energy transferred to the output of one converter due to a change in digital input code to the other converter. Specified in nV secs.

AD7528

INTERFACE LOGIC INFORMATION

DAC Selection:
Both DAC latches share a common 8-bit input port. The control input $\overline{\text{DAC A}}$/DAC B selects which DAC can accept data from the input port.

Mode Selection:
Inputs $\overline{\text{CS}}$ and $\overline{\text{WR}}$ control the operating mode of the selected DAC. See Mode Selection Table below.

Write Mode:
When $\overline{\text{CS}}$ and $\overline{\text{WR}}$ are both low the selected DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0–DB7.

Hold Mode:
The selected DAC latch retains the data which was present on DB0–DB7 just prior to $\overline{\text{CS}}$ or $\overline{\text{WR}}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

Mode Selection Table

$\overline{\text{DAC A}}$/DAC B	$\overline{\text{CS}}$	$\overline{\text{WR}}$	DAC A	DAC B
L	L	L	WRITE	HOLD
H	L	L	HOLD	WRITE
X	H	X	HOLD	HOLD
X	X	H	HOLD	HOLD

L = Low State; H = High State; X = Don't Care.

WRITE CYCLE TIMING DIAGRAM

NOTES:
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF V_{DD}.
   $V_{DD} = +5V$, $t_r = t_f = 20ns$;
   $V_{DD} = +15V$, $t_r = t_f = 40ns$;
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$
CIRCUIT INFORMATION—D/A SECTION

The AD7528 contains two identical 8-bit multiplying D/A converters, DAC A and DAC B. Each DAC consists of a highly stable thin film R-2R ladder and eight N-channel current steering switches. A simplified D/A circuit for DAC A is shown in

Figure 1. Simplified Functional Circuit for DAC A

Figure 1. An inverted R-2R ladder structure is used, that is, binary weighted currents are switched between the DAC output and AGND thus maintaining fixed currents in each ladder leg independent of switch state.

EQUIVALENT CIRCUIT ANALYSIS

Figure 2 shows an approximate equivalent circuit for one of the AD7528's D/A converters, in this case DAC A. A similar equivalent circuit can be drawn for DAC B. Note that AGND (Pin 1) is common for both DAC A and DAC B.

The current source $I_{LEAKAGE}$ is composed of surface and junction leakages and, as with most semiconductor devices, approximately doubles every 10°C. The resistor R_O as shown in Figure 2 is the equivalent output resistance of the device which varies with input code (excluding all 0s code) from 0.8 R to 2 R. R is typically 11 kΩ. C_{OUT} is the capacitance due to the N-channel switches and varies from about 50 pF to 120 pF depending upon the digital input. $g(V_{REF} A, N)$ is the Thevenin equivalent voltage generator due to the reference input voltage $V_{REF} A$ and the transfer function of the R-2R ladder.

Figure 2. Equivalent Analog Output Circuit of DAC A

CIRCUIT INFORMATION–DIGITAL SECTION

The input buffers are simple CMOS inverters designed such that when the AD7528 is operated with $V_{DD} = 5$ V, the buffer converts TTL input levels (2.4 V and 0.8 V) into CMOS logic levels. When V_{IN} is in the region of 2.0 volts to 3.5 volts the input buffers operate in their linear region and pass a quiescent current, see Figure 3. To minimize power supply currents it is recommended that the digital input voltages be as close to the supply rails (V_{DD} and DGND) as is practically possible.

The AD7528 may be operated with any supply voltage in the range $5 \leq V_{DD} \leq 15$ volts. With $V_{DD} = +15$ V the input logic levels are CMOS compatible only, i.e., 1.5 V and 13.5 V.

Figure 3. Typical Plots of Supply Current, I_{DD} vs. Logic Input Voltage V_{IN}, for $V_{DD} = +5$ V and +15 V

R2; R4	330	150	82

AD7528

APPLICATIONS INFORMATION
Application Hints
To ensure system performance consistent with AD7528 specifications, careful attention must be given to the following points:

1. GENERAL GROUND MANAGEMENT: AC or transient voltages between the AD7528 AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7528. In more complex systems where the AGND–DGND intertie is on the backplane, it is recommended that diodes be connected in inverse parallel between the AD7528 AGND and DGND pins (1N914 or equivalent).

2. OUTPUT AMPLIFIER OFFSET: CMOS DACs exhibit a code-dependent output resistance which in turn causes a code-dependent amplifier noise gain. The effect is a code-dependent differential nonlinearity term at the amplifier output which depends on V_{OS} (V_{OS} is amplifier input offset voltage). This differential nonlinearity term adds to the R/2R differential nonlinearity. To maintain monotonic operation, it is recommended that amplifier V_{OS} be no greater than 10% of 1 LSB over the temperature range of interest.

3. HIGH FREQUENCY CONSIDERATIONS: The output capacitance of a CMOS DAC works in conjunction with the amplifier feedback resistance to add a pole to the open loop response. This can cause ringing or oscillation. Stability can be restored by adding a phase compensation capacitor in parallel with the feedback resistor.

DYNAMIC PERFORMANCE
The dynamic performance of the two DACs in the AD7528 will depend upon the gain and phase characteristics of the output amplifiers together with the optimum choice of the PC board layout and decoupling components. Figure 6 shows the relation

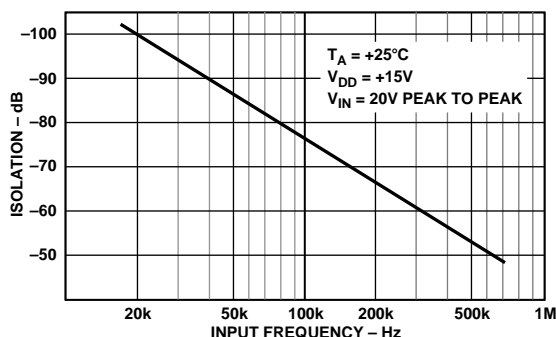

Figure 6. Channel-to-Channel Isolation

Figure 7. Suggested PC Board Layout for AD7528 with AD644 Dual Op Amp

ship between input frequency and channel to channel isolation. Figure 7 shows a printed circuit layout for the AD7528 and the AD644 dual op amp which minimizes feedthrough and crosstalk.

SINGLE SUPPLY APPLICATIONS
The AD7528 DAC R-2R ladder termination resistors are connected to AGND within the device. This arrangement is particularly convenient for single supply operation because AGND may be biased at any voltage between DGND and V_{DD}. Figure 8 shows a circuit which provides two +5 V to +8 V analog outputs by biasing AGND +5 V up from DGND. The two DAC reference inputs are tied together and a reference input voltage is obtained without a buffer amplifier by making use of the constant and matched impedances of the DAC A and DAC B reference inputs. Current flows through the two DAC R-2R ladders into R1 and R1 is adjusted until the V_{REF} A and V_{REF} B inputs are at +2 V. The two analog output voltages range from +5 V to +8 V for DAC codes 00000000 to 11111111.

Figure 8. AD7528 Single Supply Operation

Figure 9 shows DAC A of the AD7528 connected in a positive reference, voltage switching mode. This configuration is useful in that V_{OUT} is the same polarity as V_{IN} allowing single supply operation. However, to retain specified linearity, V_{IN} must be in the range 0 V to +2.5 V and the output buffered or loaded with a high impedance, see Figure 10. Note that the input voltage is connected to the DAC OUT A and the output voltage is taken from the DAC V_{REF} A pin.

## MICROPROCESSOR INTERFACE

Figure 11. AD7528 Dual DAC to 6800 CPU Interface

Figure 12. AD7528 Dual DAC to 8085 CPU Interface
PROGRAMMABLE WINDOW COMPARATOR

Figure 13. Digitally Programmable Window Comparator
(Upper and Lower Limit Detector)

In the circuit of Figure 13 the AD7528 is used to implement a programmable window comparator. DACs A and B are loaded with the required upper and lower voltage limits for the test, respectively. If the test input is not within the programmed limits, the pass/fail output will indicate a fail (logic zero).

PROGRAMMABLE STATE VARIABLE FILTER

In this state variable or universal filter configuration (Figure 14) DACs A1 and B1 control the gain and Q of the filter character-istic while DACs A2 and B2 control the cutoff frequency, f_C. DACs A2 and B2 must track accurately for the simple expression for f_C to hold. This is readily accomplished by the AD7528. Op amps are $2 \times$ AD644. C3 compensates for the effects of op amp gain bandwidth limitations.

The filter provides low pass, high pass and band pass outputs and is ideally suited for applications where microprocessor control of filter parameters is required, e.g., equalizer, tone controls, etc.

Programmable range for component values shown is f_C = 0 kHz to 15 kHz and Q = 0.3 to 4.5.
