ELECTRICAL CHARACTERISTICS

The ● denotes the specifications which apply over the full operating temperature range, otherwise specifications are at $T_A = 25^\circ\text{C}$. $V_{IN} = 1.2\text{V}$, $V_{\overline{SHDN}} = 1.2\text{V}$ unless otherwise noted.

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
Minimum Input Voltage	LT1617-1 LT1617			1.0 1.2	V V
Quiescent Current	Not Switching $V_{\overline{SHDN}} = 0\text{V}$		20	30 1	μA μA
FB Comparator Trip Point		● -1.205	-1.23	-1.255	V
FB Comparator Hysteresis			8		mV
Output Voltage Line Regulation	$1.2\text{V} < V_{IN} < 12\text{V}$		0.05	0.1	%/V
FB Pin Bias Current (Note 3)	$V_{NFB} = -1.23\text{V}$	● 1.3	2	2.7	μA
Switch Off Time			400		ns
Switch V_{CESAT}	$I_{SW} = 60\text{mA}$ (LT1617-1) $I_{SW} = 300\text{mA}$ (LT1617)		85 250	120 350	mV mV
Switch Current Limit	LT1617-1 LT1617	75 300	100 350	125 400	mA mA
\overline{SHDN} Pin Current	$V_{\overline{SHDN}} = 1.2\text{V}$ $V_{\overline{SHDN}} = 5\text{V}$		2 8	3 12	μA μA
\overline{SHDN} Input Voltage High		0.9			V
\overline{SHDN} Input Voltage Low				0.25	V
Switch Leakage Current	Switch Off, $V_{SW} = 5\text{V}$		0.01	5	μA

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: The LT1617 and LT1617-1 are guaranteed to meet specifications from 0°C to 70°C . Specifications over the -40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls.

Note 3: Bias current flows out of the NFB pin.

TYPICAL PERFORMANCE CHARACTERISTICS

PIN FUNCTIONS

SW (Pin 1): Switch Pin. This is the collector of the internal NPN power switch. Minimize the metal trace area connected to this pin to minimize EMI.

GND (Pin 2): Ground. Tie this pin directly to the local ground plane.

NFB (Pin 3): Feedback Pin. Set the output voltage by selecting values for R1 and R2 (see Figure 1):

$$R1 = \frac{|V_{OUT}| - 1.23}{\frac{1.23}{R2} + (2 \cdot 10^{-6})}$$

SHDN (Pin 4): Shutdown Pin. Tie this pin to 0.9V or higher to enable the device. Tie below 0.25V to turn off the device.

V_{IN} (Pin 5): Input Supply Pin. Bypass this pin with a capacitor as close to the device as possible.

The LT1617 uses a constant off-time control scheme to provide high efficiencies over a wide range of output current. Operation can be best understood by referring to the block diagram in Figure 1. Q1 and Q2 along with R3 and R4 form a bandgap reference used to regulate the output voltage. When the voltage at the NFB pin is slightly below -1.23V , comparator A1 disables most of the internal circuitry. Output current is then provided by capacitor C2, which slowly discharges until the voltage at the NFB pin goes above the hysteresis point of A1 (typical hysteresis at the NFB pin is 8mV). A1 then enables the internal circuitry, turns on power switch Q3, and the current in

inductors L1 and L2 begins ramping up. Once the switch current reaches 350mA, comparator A2 resets the one-shot, which turns off Q3 for 400ns. L2 continues to deliver current to the output while Q3 is off. Q3 turns on again and the inductor currents ramp back up until the switch current reaches 350mA, then A2 again resets the one-shot. This switching action continues until the output voltage is charged up (until the NFB pin reaches -1.23V), then A1 turns off the internal circuitry and the cycle repeats. The LT1617-1 operates in the same manner, except the switch current is limited to 100mA (the A2 reference voltage is 12mV instead of 42mV).

APPLICATIONS INFORMATION

Choosing an Inductor

Several recommended inductors that work well with the LT1617 and LT1617-1 are listed in Table 1, although there are many other manufacturers and devices that can be used. Consult each manufacturer for more detailed information and for their entire selection of related parts. Many different sizes and shapes are available. Use the equations and recommendations in the next few sections to find the correct inductance value for your design.

Inductor Selection—Inverting Regulator

The formula below calculates the appropriate inductor value to be used for an inverting regulator using the LT1617 or LT1617-1 (or at least provides a good starting point). This value provides a good tradeoff in inductor size and system performance. Pick a standard inductor close to this value (both inductors should be the same value). A larger value can be used to slightly increase the available output current, but limit it to around twice the value calculated below, as too large of an inductance will increase the output voltage ripple without providing much additional output current. A smaller value can be used (especially for systems with output voltages greater than 12V) to give a smaller physical size. Inductance can be calculated as:

$$L = 2 \left(\frac{|V_{OUT}| + V_D}{I_{LIM}} \right) t_{OFF}$$

where $V_D = 0.4V$ (Schottky diode voltage), $I_{LIM} = 350mA$ or $100mA$, and $t_{OFF} = 400ns$.

For higher output voltages, the formula above will give large inductance values. For a 2V to 20V converter (typical LCD bias application), a $47\mu H$ inductor is called for with the above equation, but a $10\mu H$ or $22\mu H$ inductor could be used without excessive reduction in maximum output current.

Inductor Selection—Inverting Charge Pump Regulator

For the inverting regulator, the voltage seen by the internal power switch is equal to the sum of the absolute value of the input and output voltages, so that generating high output voltages from a high input voltage source will often exceed the 36V maximum switch rating. For instance, a 12V to –30V converter using the inverting topology would generate 42V on the SW pin, exceeding its maximum rating. For such a system, an inverting charge pump is the best topology.

The formula below calculates the approximate inductor value to be used for an inverting charge pump regulator using the LT1617. As for the boost inductor selection, a larger or smaller value can be used. For designs with varying V_{IN} such as battery powered applications, use the minimum V_{IN} value in the equation below.

$$L = \frac{|V_{OUT}| - V_{IN(MIN)} + V_D}{I_{LIM}} t_{OFF}$$

Current Limit Overshoot

For the constant off-time control scheme of the LT1617, the power switch is turned off only after the 350mA (or 100mA) current limit is reached. There is a 100ns delay between the time when the current limit is reached and when the switch actually turns off. During this delay, the inductor current exceeds the current limit by a small amount. The peak inductor current can be calculated by:

$$I_{PEAK} = I_{LIM} + \left(\frac{V_{IN(MAX)} - V_{SAT}}{L} \right) 100ns$$

Where $V_{SAT} = 0.25V$ (switch saturation voltage). The current overshoot will be most evident for systems with high input voltages and for systems where smaller inductors are used.

APPLICATIONS INFORMATION

tor values are used. This overshoot can be beneficial as it helps increase the amount of available output current for smaller inductor values. This will be the peak current seen by the inductor (and the diode) during normal operation. For designs using small inductance values (especially at input voltages greater than 5V), the current limit overshoot can be quite high. Although it is internally current limited to 350mA, the power switch of the LT1617 can handle larger currents without problem, but the overall efficiency will suffer. Best results will be obtained when I_{PEAK} is kept below 700mA for the LT1617 and below 400mA for the LT1617-1.

Capacitor Selection

Low ESR (Equivalent Series Resistance) capacitors should be used at the output to minimize the output ripple voltage. Multilayer ceramic capacitors are the best choice, as they have a very low ESR and are available in very small packages. Their small size makes them a good companion to the LT1617's SOT-23 package. Solid tantalum capacitors (like the AVX TPS, Sprague 593D families) or OS-CON capacitors can be used, but they will occupy more board area than a ceramic and will have a larger ESR. Always use a capacitor with a sufficient voltage rating.

Ceramic capacitors also make a good choice for the input decoupling capacitor, which should be placed as close as possible to the LT1617. A 4.7μF input capacitor is sufficient for most applications. Table 2 shows a list of several capacitor manufacturers. Consult the manufacturers for more detailed information and for their entire selection of related parts.

Diode Selection

For most LT1617 applications, the Motorola MBR0520 surface mount Schottky diode (0.5A, 20V) is an ideal choice. Schottky diodes, with their low forward voltage drop and fast switching speed, are the best match for the LT1617. For higher output voltage applications the 30V MBR0530 can be used. Many different manufacturers make equivalent parts, but make sure that the component is rated to handle at least 0.5A. For LT1617-1 applications, a Phillips BAT54 or a Central Semiconductor CMDSH-3 works well.

Lowering Output Voltage Ripple

Using low ESR capacitors will help minimize the output ripple voltage, but proper selection of the inductor and the output capacitor also plays a big role. The LT1617 provides energy to the load in bursts by ramping up the inductor current, then delivering that current to the load. If too large of an inductor value or too small of a capacitor value is used, the output ripple voltage will increase because the capacitor will be slightly overcharged each burst cycle. To reduce the output ripple, increase the output capacitor value or add a 100pF feed-forward capacitor in the feedback network of the LT1617 (see the circuits in the Typical Applications section). Adding this small, inexpensive 100pF capacitor will greatly reduce the output voltage ripple.
